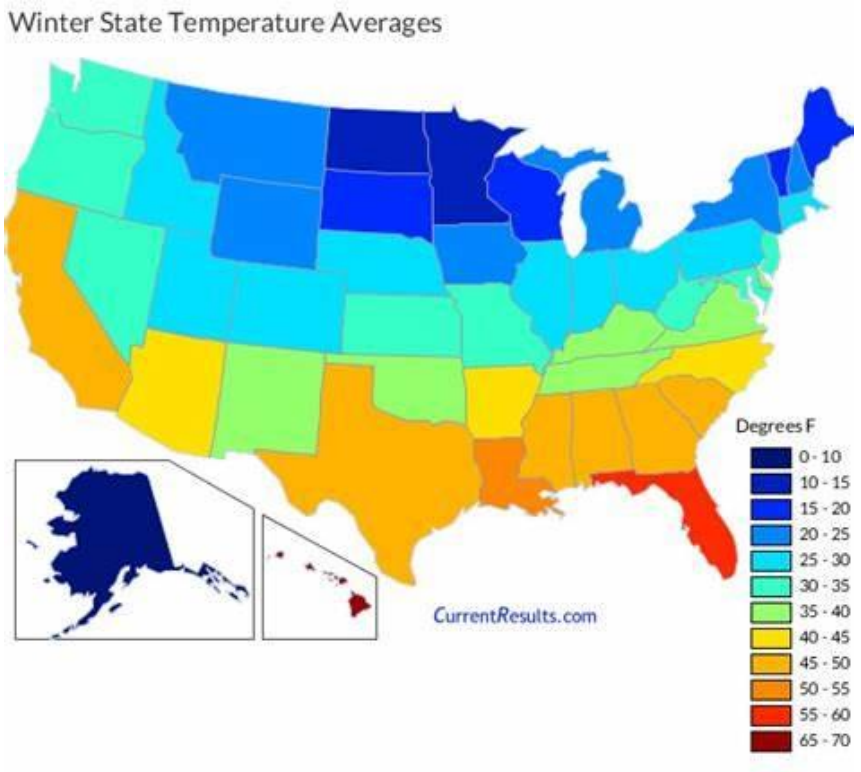
Historic Distribution of *Aedes aegypti* in Georgia

GMCA / Rosmarie Kelly / Oct 16-18, 2019

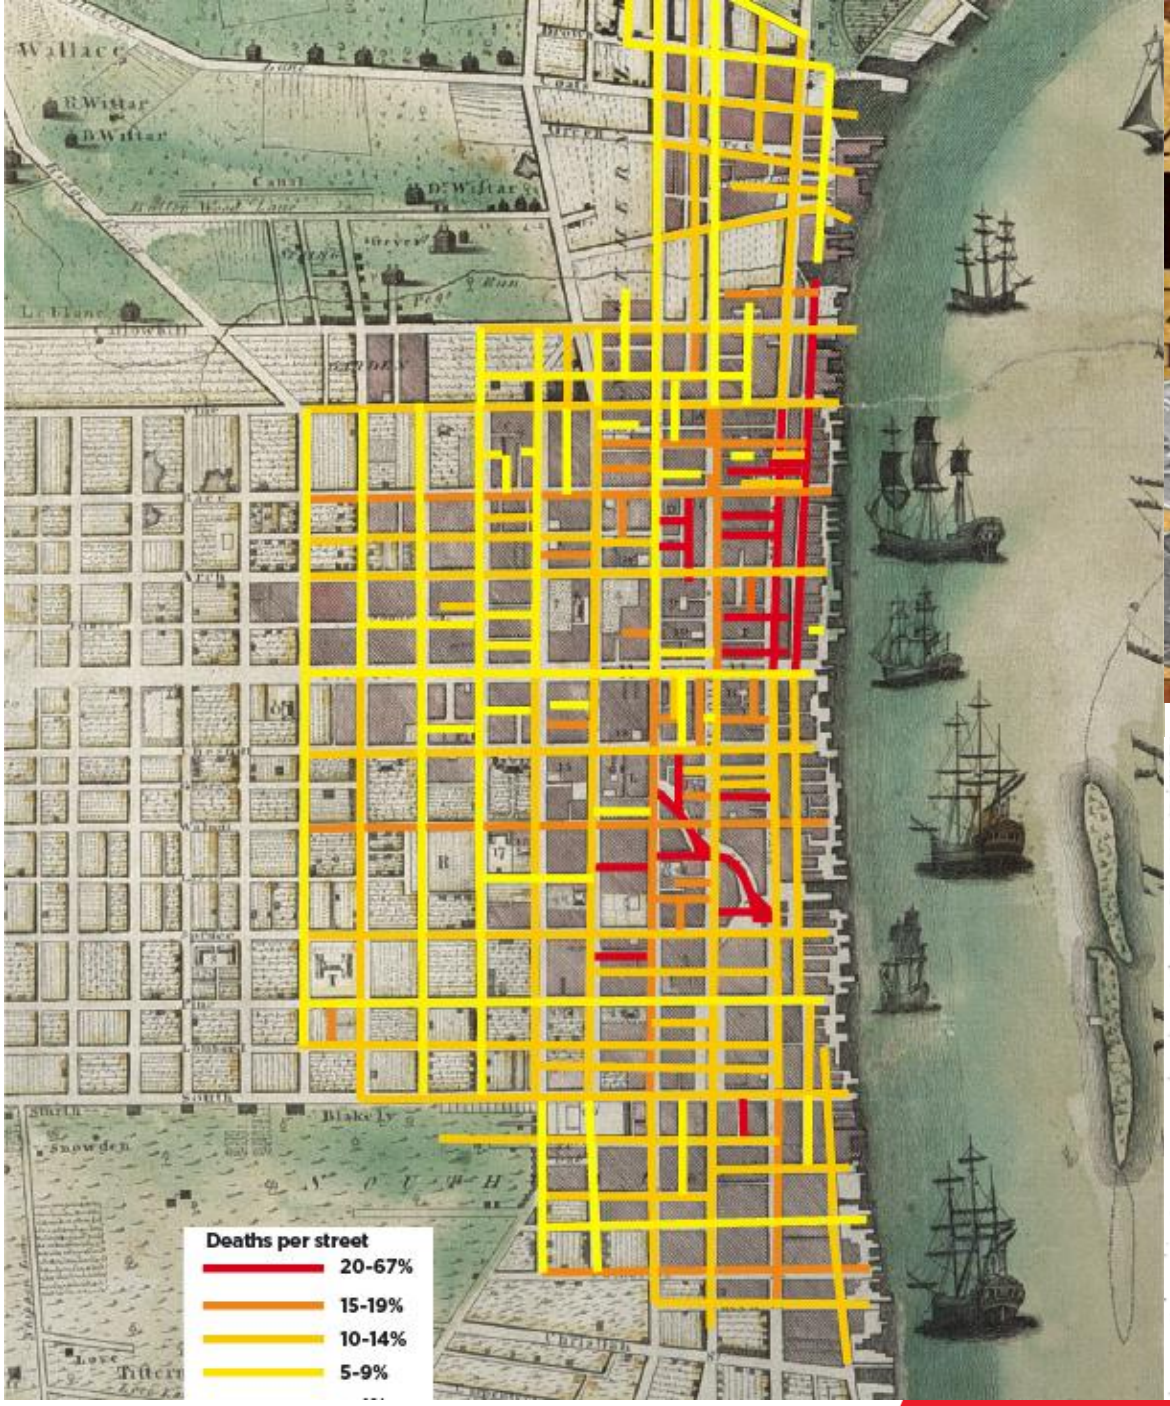
However, an overwintering population of *Aedes aegypti* has been documented in the Capitol Hill neighborhood of Washington, DC, since 2011.

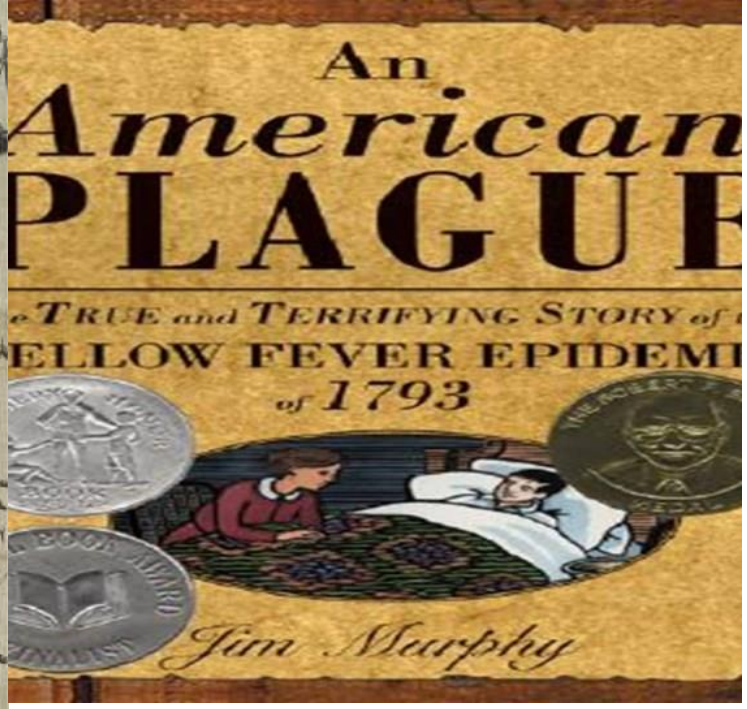
- *Aedes aegypti* is an invasive, highly anthropophilic mosquito and a major vector for yellow fever, dengue, Zika, and chikungunya.
- Population persistence in the continental United States is reportedly limited to southward of the average 50°F winter isotherm, which in the east, bisects Alabama, Mississippi, Georgia, and South Carolina.



- The first yellow fever outbreaks in the United States occurred in late 1690s.
- Nearly 100 years later, in the late summer of 1793, refugees from a yellow fever epidemic in the Caribbean fled to Philadelphia.
  - Within weeks, people throughout the city were experiencing symptoms.
  - By the middle of October, 100 people were dying from the virus every day.
  - Caring for the victims so strained public services that the local city government collapsed.
  - Philadelphia was also the seat of the United States government at the time, but federal authorities simply evacuated the city in face of the raging epidemic.

Dead House on the Schuylkill during the yellow fever in Philadelphia in 1793, David Johnson Kennedy, Watercolor, Historical Society of Pennsylvania.





MALIGNANT FEVER,

LATELY PREVALENT IN

PHILADELPHIA:

WITH A STATEMENT OF THE

PROCEEDINGS

THAT TOOK PLACE ON THE SUBJECT IN DIFFERENT PARTS OF THE

UNITED STATES.

BY MATHEW CAREY.

PHILADELPHIA:

PRINTED BY THE AUTHOR.

- A yellow fever epidemic in Philadelphia in 1793 was one of the main reasons why the newly created United States of America consolidated their plans to place the capitol in Washington D.C., while the business community of the U.S. moved to New York.
- Prior to the epidemic, the government, as well as the big-business community, was located in Philadelphia, and it was thought that Philadelphia would become the capitol of U.S.
- However, the yellow fever epidemic literally changed U.S. history, which is why the White House is in Washington, but Wall Street is located in New York.

Nearly 700 people in Savannah, Georgia died from yellow fever in 1820, including two local physicians who lost their lives caring for the stricken. Several other epidemics followed, including 1854 and 1876.

Memphis suffered several epidemics during the 1870s, culminating in the 1878 epidemic (called the Saffron Scourge of 1878), with more than 5,000 fatalities in the city.

Yellow fever burial, Memphis, Tennessee, September 21, 1878. Illustration by unknown creator, published by Frank Leslie's Illustrated Newspaper.

The entire Mississippi River Valley from St. Louis south was affected, and tens of thousands fled the stricken cities of New Orleans, Vicksburg, and Memphis. An estimated 120,000 cases of yellow fever resulted in some 20,000 deaths.

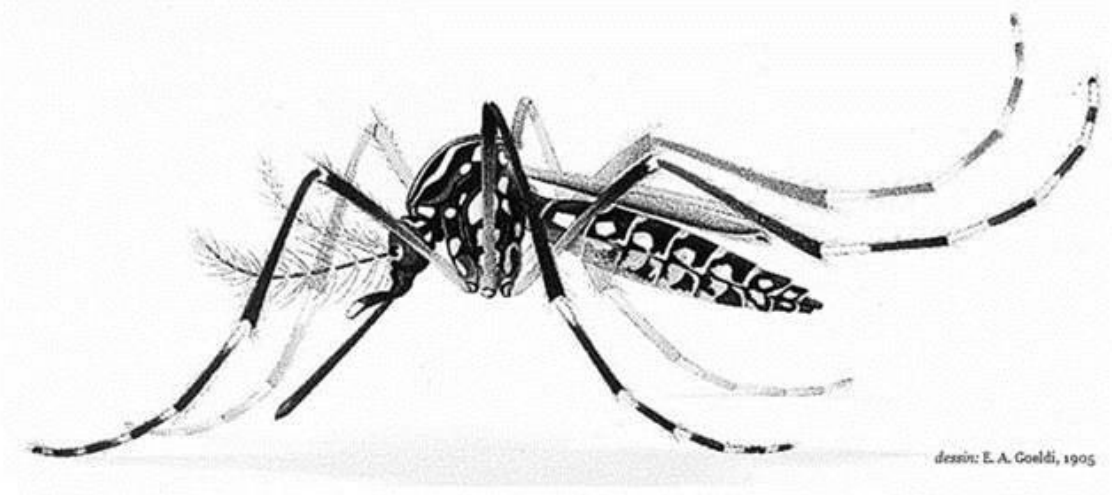
The TOWN MOSQUITO – Le MOUSTIQUE de la VILLE



AEDES AEGYPTI

The VIRUS CARRIER – Le PORTEUR de VIRUS

Yellow fever/la fièvre jaune – dengue – zika - chikungunya

Deny this ONE mosquito species the water pockets it needs to hatch its larvae near people and quickly solve <u>four</u> public health problems in <u>one</u> targeted effort.

MosquitoPundit blog

Surveys for *Aedes aegypti* were of two types prior to 1958:

- The first involved only the recording of premises found breeding the mosquito during control procedures.
  - The sample size was usually large because all premises were inspected as part of the control program.
- The second type of survey had no connection with control work.
  - Instead, premises on which *Ae. aegypti* breeding was considered possible were inspected in surveys lasting one week or less in a community.
  - The sample size was relatively small, and the ability of the surveyor to select likely premises was important in determining results.

THE 1958 *AEDES AEGYPTI* DISTRIBUTION IN THE UNITED STATES

Milton E Tinker and George R Hayes, Jr
CDC Public Health Service, Atlanta, GA
Mosquito News, June 1959

In 1958, three types of surveys were used to develop three sets of facts:

1. quantitative urban surveys of 19 cities in which blocks inspected were selected by random sampling techniques to obtain a statistically valid determination of the magnitude of the species population:
2. qualitative urban surveys of 65 cities where the presence of the species was determined in as short a time as possible;
3. and exploratory rural surveys of 9 counties in which likely premises were inspected to discover breeding of the species in such areas.

Qualitative Urban	Quantitative Urban	Exploratory Rural	Number of Premises Surveyed	Results
Brunswick			21	+
Columbus			38	+
Macon			38	+
Savannah			56	-
Thomasville			11	+
Tifton			112	-
Waycross			15	+
	Atlanta		518	11.6%
	Gainesville		225	0.0%
		Thomas County	53	-
		Dodge County	155	-

Of the 42 cities where seaport and airport facilities were inspected by the Division of Foreign Quarantine, *Ae. aegypti* was found in only one, Savannah, Georgia, where they were not found during CDC surveys.

Since 3 subsequent surveys of the Savannah port facilities by the Division of Foreign Quarantine and a survey of the whole city by CDC have failed to disclose further infestations, this positive finding was probably a temporary import.

NOTE: *Aedes aegypti* has continued to be found occasionally and in small numbers in Savannah

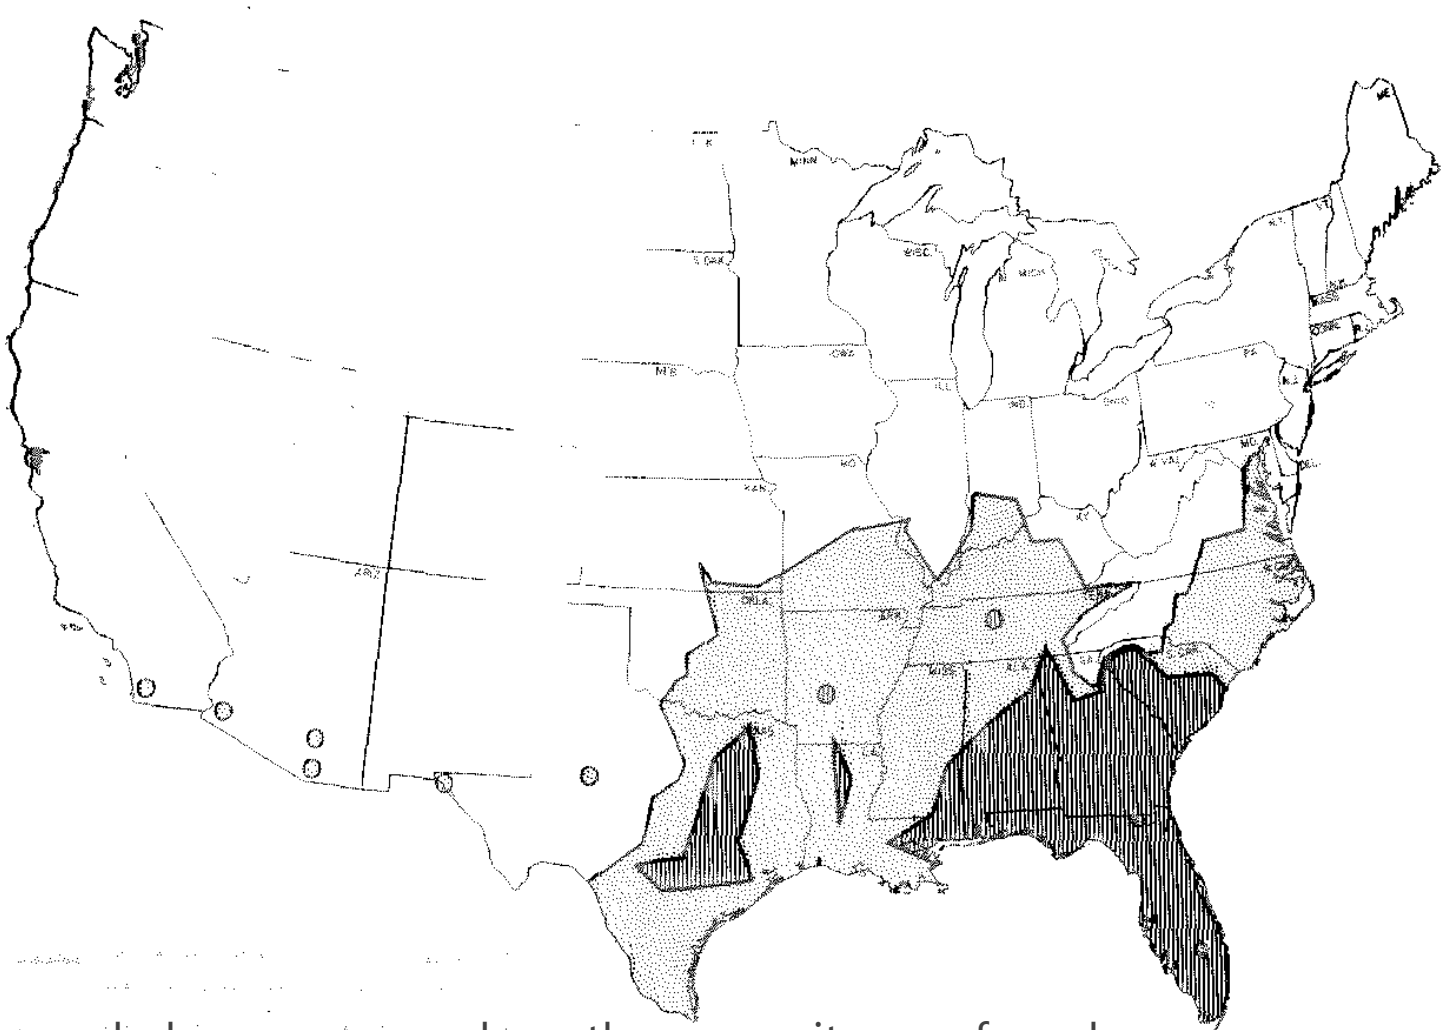
Distribution of *Aedes aegypti* in the US, 1959



DISTRIBUTION OF *AEDES AEGYPTI* INFESTATIONS IN THE UNITED STATES

HARVEY B. MORLAN AND MILTON E. TINKER
American Journal of Tropical Medicine & Hygiene, 1965

A Public Health Service program to eradicate *Aedes aegypti* from the United States was initiated by the Communicable Disease Center (CDC) with funds appropriated by Congress in October 1963. From 1956 through 1962, CDC surveys conducted in cooperation with state and local departments of health in 440 communities of 262 countries had shown *Ae. aegypti* in 101 counties of nine southeastern states.

TABLE 1

Summary of Aedes aegypti *survey, 1964*

State	Counties		Communities		Premises	
	Surveyed	Infested	Surveyed	Infested	Surveyed	Infested
Ala.	64	46	693	228	6,597	462
Ark.	23	2	252	2	4,385	3
Fla.	58	29	538	68	5,812	169
Ga.	143	72	844	159	22,253	396
La.	48	1	435	2	13,927	13
Miss.	72	14	493	31	6,601	53
N. C.	17	1	158	1	2,473	1
Okla.	15	0	183	0	3,980	0
S. C.	39	15	413	44	4,582	87
Tenn.	26	2	217	3	3,924	5
Texas	134	21	1,031	28	15,974	42
Total	639	203	5,257	566	90,508	1,231

The 1964 survey consisted of inspection of premises most likely to be infested in each community in the county. The size of the survey in a county differed, based on human population, urban nature, and number of communities. The general requirement was to survey one percent of the premises in the county.

The following table shows the county inspected with # premises inspected/# of premises with *Ae. aegypti*.

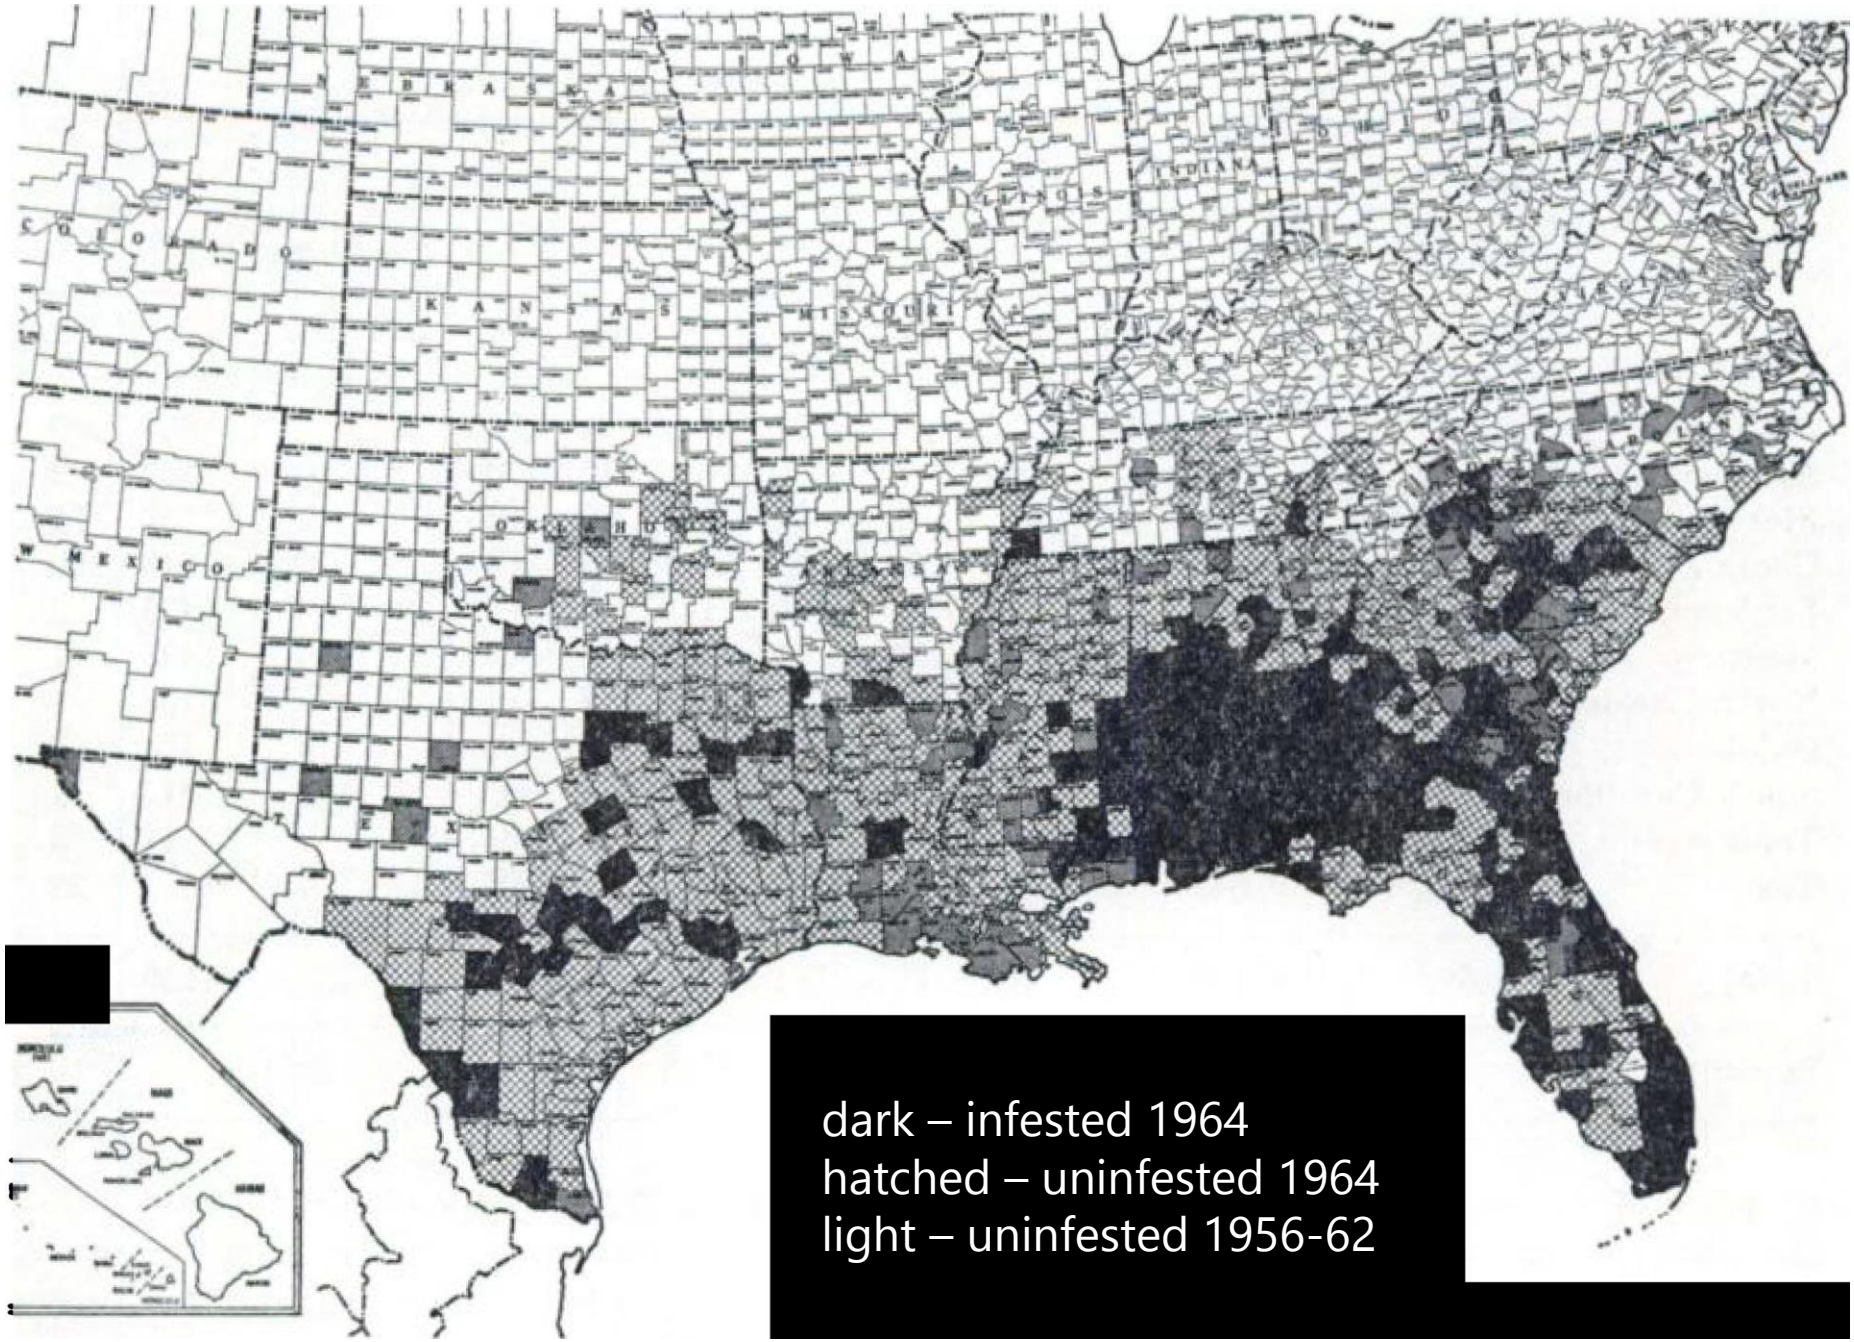
CITIZENS LEAVING THEIR CONTRIBUTIONS IN THE POST-OFFICE YELLOW-FEVER BOX.

https://www.alabamapioneers.com/yellow-fever-epidemics-and-free-land/

Infestations of *Ae. aegypti* were found in 566 communities in 203 counties or parishes.

- The states of Alabama, Florida, and Georgia had the largest number of infestations, with 147 of the 203 infested counties, or 72%.
- Of the 203 counties infested:
  - 78 had been found infested previously,
  - 12 had been negative on previous inspection, and
  - 113 had not been surveyed.
- Of the 436 negative counties:
  - 52 had been negative on previous inspection,
  - 14 previously infested, and
  - 370 had not been surveyed.
- Of the counties surveyed, 32% were infested.
- The program to eradicate *Ae. aegypti* from the continental United States, which began in 1964, never reached its ultimate goal and was terminated in 1969 because of lack of funds.



dark – infested 1964
hatched – uninfested 1964
light – uninfested 1956-62

The 1964 survey provided definite information on infested communities, but negative findings did not provide conclusive evidence of the absence of *Ae. aegypti*. The survey extended over a large geographic area, but inspection was limited to about one percent of the total number of premises.

Size of communities infested by Aedes aegypti, *1964*

State	Size of community (no. population)												Total

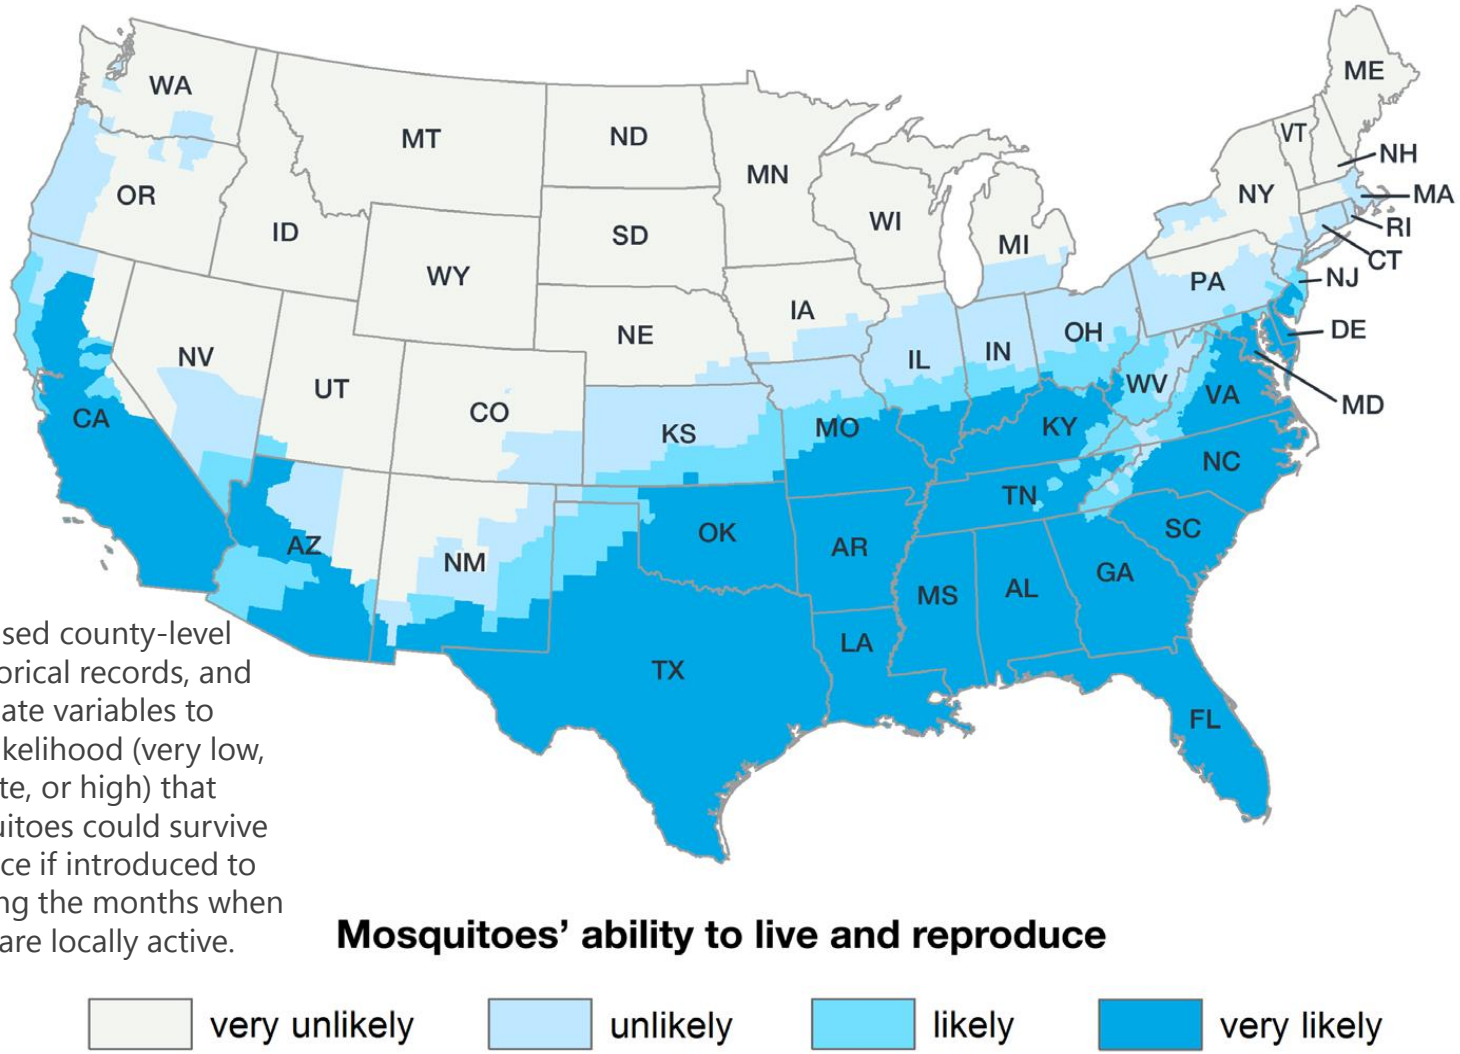
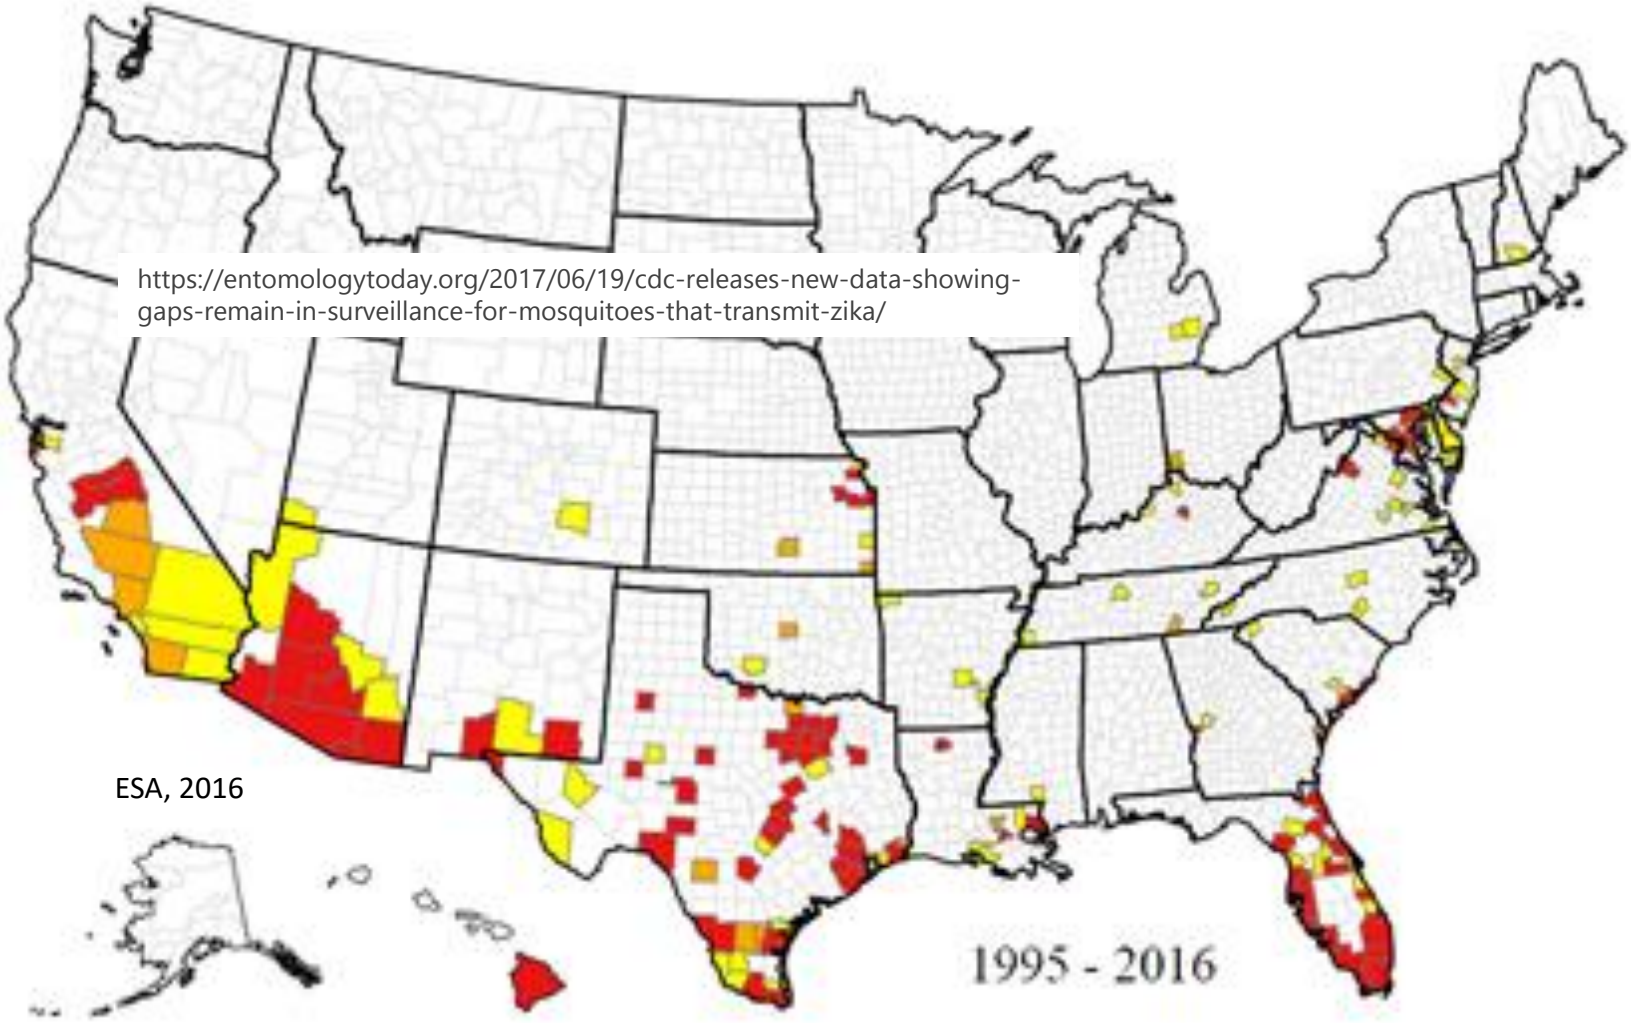
CDC's best estimate of the potential range of *Ae. aegypti* in the US



The model used county-level records, historical records, and suitable climate variables to predict the likelihood (very low, low, moderate, or high) that these mosquitoes could survive and reproduce if introduced to an area during the months when mosquitoes are locally active.

https://www.cdc.gov/zika/vector/range.html, 2018



This map shows counties where *Aedes aegypti* was reported between January 1, 1995 and March 2016. Counties shown in yellow had records for one year within that time period; those shown in orange had two years of presence records, and those shown in red had three or more years of presence records.
